I. Introduction

Heart disease is the leading cause of death for men, women, and people of most racial and ethnic groups. One of the significant causes of heart disease in individuals is high cholesterol. High cholesterol can lead to heart attacks and strokes when blood clots form and block blood flow]. Understanding the relationship between cholesterol levels and the presence of heart disease among different age groups is important for prevention and detection.

This project investigates how cholesterol levels correlate with different age groups. To find this correlation, a dataset from Kaggle will be used, which includes variables such as age, gender, and total cholesterol (totChol). By analyzing this dataset, the study aims to provide insight into how age influences cholesterol levels and how this may affect the risk of developing heart disease.
